Managing dependencies is more than running "composer update"

Nils Adermann

@naderman

Private Packagist

https://packagist.com

What are Dependencies?

- Services
 - APIs
 - Client-side Integrations (OAuth / External JS / Analytics / ...)
- Software
 - Libraries
 - Programs / Tools
- External Assets

What is Dependency Management?

- Assembly
- Dependency Change Management
- Risk Analysis & Reduction

May happen at build time or at runtime

Dependency Assembly

- Installation of Libraries, Tools, etc.
 - composer install
 - apt-get install foo
 - Application of Configuration Management (Puppet, Chef, Ansible, Salt, ...)
- Configuration for Connections to Services, external APIs
 - Authentication
 - Glue Code
- Connection to Services (usually at Runtime)

Dependency Assembly

Past:

- Step-by-Step installation instructions
- Readmes, Delete and reinstall individual packages

Today:

- Description of a system state (e.g. composer.json, top.sls)
- Tools to move the system into the state (e.g. composer, salt)

Dependency Change Management

- Dependency Change
 - Adding, Removing, Updating, Replacing of Libraries
 - Replacing APIs
 - composer update
- Dependency Change Management
 - Balance Risks, Consequences, Cost & Advantages
 - Architecture Decisions which enable "Change"
 - Example: Abstraction to replace concrete service

Risk Analysis: Availability

Affects Assembly

Examples:

- Open Source Library deleted
- Payment Service unavailable
- EU VATId Service out of order
- Jenkins not accessible

Risk Reduction: Availability

- Software is available when you have a copy
 - composer cache
 - Forks
 - Private Packagist or Satis
- Services are available depending on external factors
 - Can the service be called asynchronously?
 - e.g. run VATId check after payment
 - e.g. Private Packagist inits package in worker, no GitHub access in controller
 - Are errors clearly presented to users?
 - e.g. low timeouts, error messages when external Service X not available

Risk Analysis: Compatibility

Affects Change Management

Examples:

- BC Break in Library Update
- API Semantics change:
 - Payment API no longer supports credit card tokens, only payment tokens valid for Apple
 Pay etc., too

Risk Reduction: (New) Dependencies

Quality Criteria for software libraries (and services)

- Number of Maintainers / Developers
- Actively Developed?
- How many users?
 - Packagist shows installation count
- Where is a library being installed from?
 - GitHub, self-hosted svn server? -> Availability
- Alternatives / how easy to replace? Complexity?
 - Could you take over maintenance?

Risk Reduction: Compatibility

Semantic Versioning (Semver) promises Compatibility

X.y.Z

- Must be used consistently
- Only valuable if BC/Compatibility promise formalized
 - See http://symfony.com/doc/current/contributing/code/bc.html
- Otherwise choose narrower Version Constraints, check more frequently
 - e.g. ~1.2.3 instead of ^1.2.3

Risk Reduction: Compatibility

- Automated
 - Tests
 - Static Analysis
- Manual
 - Read Changelogs (and write them!)
 - Experience which libraries break BC

Risk Reduction: Compatibility

- "composer update"
 - no isolation of problems unless run very frequently
- "composer update <package...>"
 - explicit conscious updates
- "composer update --dry-run [<package...>]"
 - Understanding and preparing effects of updates

```
{ "name": "zebra/zebra",
    "require": {
        "horse/horse": "^1.0" }}

{ "name": "giraffe/giraffe",
        "require": {
        "duck/duck": "^1.0" }}
```

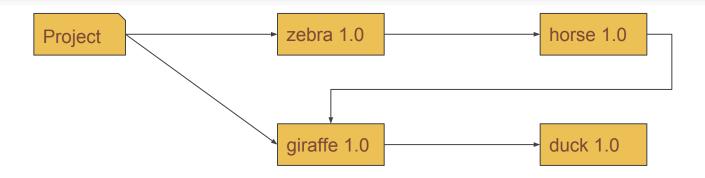

```
{ "name": "horse/horse",
    "require": {
        "giraffe/giraffe": "^1.0" }}

{ "name": "duck/duck",
    "require": {}}
```

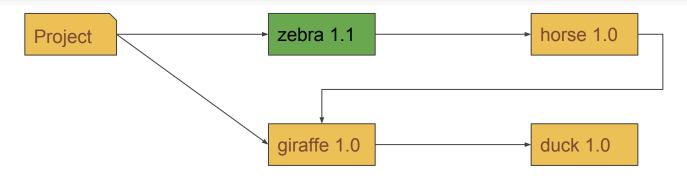

```
{
    "name": "my-project",
    "require": {
        "zebra/zebra": "^1.0",
        "giraffe/giraffe": "^1.0"
}
```

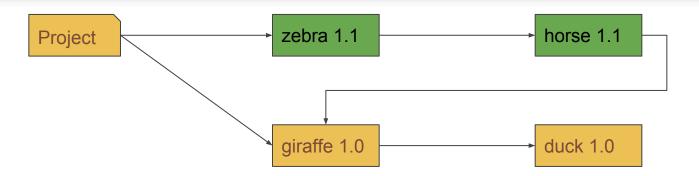

Now each package releases 1.1

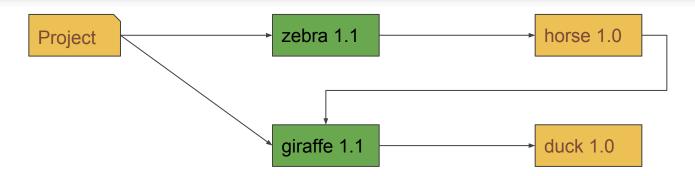

\$ composer update --dry-run zebra/zebra
Updating zebra/zebra (1.0 -> 1.1)

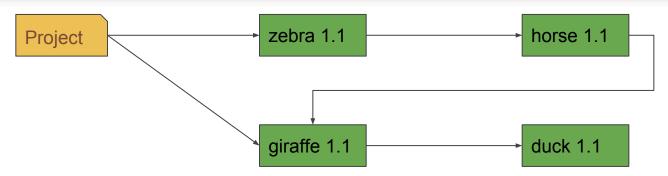

\$ composer update --dry-run zebra/zebra --with-dependencies
 Updating horse/horse (1.0 -> 1.1)
 Updating zebra/zebra (1.0 -> 1.1)

\$ composer update --dry-run zebra/zebra giraffe/giraffe
 Updating zebra/zebra (1.0 -> 1.1)
 Updating giraffe/giraffe (1.0 -> 1.1)

\$ composer update zebra/zebra giraffe/giraffe --with-dependencies Updating duck/duck (1.0 -> 1.1) Updating giraffe/giraffe (1.0 -> 1.1) Updating horse/horse (1.0 -> 1.1) Updating zebra/zebra (1.0 -> 1.1)

The Lock File

- Contents

- all dependencies including transitive dependencies
- Exact version for every package
- download URLs (source, dist, mirrors)
- Hashes of files

Purpose

- Reproducibility across teams, users and servers
- Isolation of bug reports to code vs. potential dependency breaks
- Transparency through explicit updating process

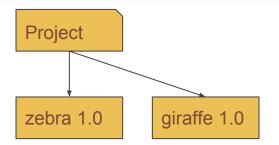

Commit The Lock File

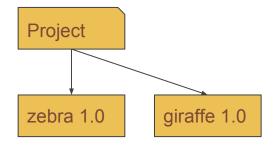

- If you don't
 - composer install without a lock file is a composer update
 - Affects Assembly
 - Conflict can randomly occur on install
 - You may not get the same code
 - You no longer manage change Change is managing you!
- The lock file exists to be committed!

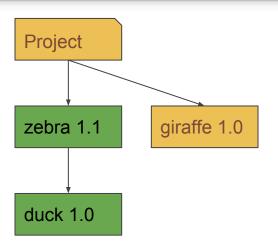

- composer.lock cannot be merged without conflicts
 - contains hash over relevant composer.json values
- git checkout <refspec> -- composer.lock
 - git checkout master -- composer.lock
- Repeat: composer update <list of deps>
 - Store parameters in commit message
 - Separate commit for the lock file update

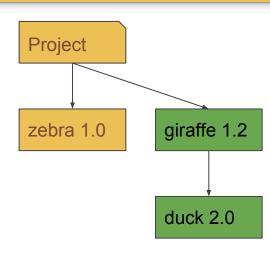

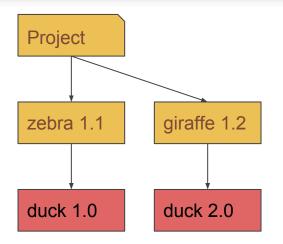

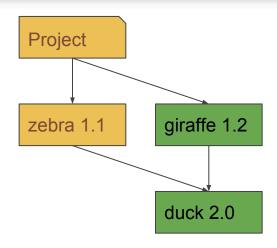

Merge results in invalid dependencies

Rerunning update is safe

Risk Analysis: Compliance / Legal

Affects Change Management

Examples:

- Viral Copy-Left License not compatible with proprietary product
- Terms of Service
 - May I use an API for my services?
 Cloudflare / packagist.org
 - How much time do I have when a supplier terminates the service?
 - SLA with sufficient support?

Risk Minimization: Compliance / Legal

- Software dependency license must fit product license or customer requirements
 - composer licenses
 - Private Packagist License Review
- Terms of Service / SLA / Contracts
 - Criteria for selection
 - Negotiable
 - Strong dependencies justify financial expenses to create security

Assessing & Managing Risk

- Formulate a Plan B
- Identify problems which are probable and which have great effects
- **Dependencies are great!** They can save tons of money and time
- Only spend resources on reducing risk until the risk is acceptable

Summary

- composer update [--dry-run] <package>
- git checkout
branch> -- composer.lock
- Formalize BC promises for users of your libraries
- SemVer: Don't be afraid to increase the major version
- Document changes to dependencies

- Have a plan B
- Don't waste resources on potential problems which are unlikely to occur or have insignificant effects
- Dependencies are great!
 Benefit usually greater than cost

Developers must consider dependency management from a business perspective Business / Management must not ignore risk from software dependencies

Thank you!
